

Morphological variation in Central American leaf-litter anoles: *Norops humilis*, *N. quaggulus* and *N. uniformis*

GUNTHER KÖHLER, SARAH ALT, CHRISTOPH GRÜNFELDER, MATTHIAS DEHLING & JAVIER SUNYER

Abstract. Pholidosis, morphometrics, and hemipenis morphology were studied in the Central American anole species *Norops humilis*, *N. quaggulus*, and *N. uniformis*. Head scalation illustrations of each species and a distribution map are provided. In hemipenis morphology, the three taxa are distinct. However, very little differentiation in pholidotic and morphometric characters is documented. Interspecific variation was observed in several characters but with overlap of the documented ranges. A discriminant function analysis based on five pholidotic characters yielded a scatter diagram that showed large overlap between the clusters of the three taxa.

Key words. Reptilia, Squamata, Iguanidae, *Norops humilis*, *N. quaggulus*, *N. uniformis*, distribution, morphological variation, hemipenis morphology.

Resumen. Se estudia la folidosis, morfometría y morfología del hemipene de los anolis centroamericanos *Norops humilis*, *N. quaggulus* y *N. uniformis*. Se proveen ilustraciones de las escamas de la cabeza así como un mapa de distribución para estas especies. Las tres especies son distintivas en cuanto a la morfología del hemipene aunque se documenta muy poca diferencia en caracteres morfométricos y de folidosis. Se observa variación interespecífica en ciertos caracteres pero existe solapamiento de los rangos documentados. Un análisis de función discriminante basado en cinco caracteres de folidosis produjo un diagrama disperso que muestra gran solapamiento entre los rangos de los tres taxa.

Introduction

In 1863, W. PETERS described *Anolis humilis* based on two female syntypes (now ZMB 500, 55223) from “Veragua” [probably western Panama; see SAVAGE 1970]. COPE (1885) described *Anolis quaggulus* (based on an adult male [now USNM 24979 according to COCHRAN 1961] from “San Juan river, Nicaragua”) and *Anolis uniformis* (based on “many specimens from Guatemala from Henry Hague, and one from Yucatan from Arthur Scott” [COPE 1885:393]). In 1935, STUART named *Anolis ruthveni* (based on an adult male from “about two miles north of Santa Teresa, El Petén, Guatemala”). In his monograph of Costa Rican lizards, TAYLOR (1956) described another taxon related to this cluster of species: *Anolis humilis marsupialis* based on a series of seven specimens from

“about 15 km WSW of San Isidro del General along the Dominical Road” (probably Puntarenas Province, or near the boundary of this province in San José Province).

BARBOUR (1934) and most subsequent authors (e.g., STUART 1948, 1963, PETERS & DONOSO-BARROS 1970) placed *quaggulus* in the synonymy of *humilis*, and *ruthveni* in the synonymy of *uniformis*, respectively. Also, these authors considered *uniformis* as a subspecies of *humilis*, a view considered valid until MEYER & WILSON (1972) presented evidence for species status of *uniformis*, mostly based on differences in male dewlap coloration. Subsequent authors (e.g., FITCH & SEIGEL 1984, SAVAGE & VILLA 1986, KÖHLER 2000) followed the conclusion that *humilis* and *uniformis* represent two separate species. Recently, KÖHLER et al. (2003) resurrected *quaggulus* as a valid species distinct from

humilis, mostly based on differences in hemipenial morphology, and they also concluded that *Anolis humilis marsupialis* remains in the synonymy of *N. humilis*.

Here, we report upon the results of our study on the interspecific variation in pholidosis, morphometrics, and hemipenis morphology of the small leaf litter anoles currently assigned to the species *Norops humilis*, *N. quaggulus*, and *N. uniformis*.

Materials and methods

The species descriptions are based on specimens examined by the authors (see Appendix). The distribution map is based on specimens examined by the authors (closed symbols) and on additional records (open symbols) taken from LEE (1996), and SAVAGE (2002). Measurements and scalation data were taken from 37 *Norops humilis* (27 males, 10 females), 45 *N. quaggulus* (26 males, 19 females), and 29 *N. uniformis* (19 males, 10 females). Abbreviations for museum collections follow those of LEVITON et al. (1985). Nomenclature of scale characters follows that of KÖHLER (2003). Terminology for hemipenial morphology follows that of MYERS et al. (1993) and SAVAGE (1997). All measurements were made using precision calipers and were rounded to the nearest 0.1 mm. Head length was measured from the tip of the snout to the anterior margin of the ear opening. Snout length was measured from the tip of the snout to the anterior border of the orbit. Head width was determined as the distance between the oral ricti. Dorsal scales were counted at the middle portion of the trunk along a paravertebral line, and ventral scales were counted at the middle portion of the trunk along the midline. Tail height and width were measured at the point reached by the heel of the extended hind leg. Subdigital lamellae were counted on phalanges ii to iv of the 4th toe. Abbreviations used are SVL (snout-vent length), HL (head length) and HW (head width). Statistics were performed using the computer program Statistica ver-

sion 6.1. To assess whether the means of two groups are statistically different t-tests were performed ($p < 0.005$). Discriminant Function Analyses were used to test if the taxa in question could be differentiated by a combination of several pholidotic characters.

Results

Interspecific variation is most evident in hemipenis morphology with each species having a distinct hemipenis shape and surface ornamentation. The hemipenis of *Norops humilis* is a medium-sized organ with well-developed elongate lobes and with a strongly calyculate surface on both the truncus and the lobes. In *N. quaggulus*, the hemipenis is relatively small with short and stout lobes and without a strongly calyculate surface on either the truncus or the lobes. *Norops uniformis* has a medium-sized bilobate hemipenis with the sulcus spermaticus bifurcating at base of apex and the branches continuing to tips of lobes; an asulcate ridge is present; the lobes are strongly calyculate and the truncus bears transverse folds. In our material, intraspecific variation in hemipenis morphology is restricted to size differences of the organ with smaller individuals having smaller hemipenes.

In contrast to the documented interspecific differences in hemipenis morphology, very little differentiation in pholidotic and morphometric characters could be documented. See Table 1 for variation in selected measurements and proportions and scale characters. Interspecific variation was observed in several characters but with large overlap of the documented ranges. Statistically significant differences ($p < 0.005$) were observed between *Norops uniformis* and the other two species in the following characters: (1) number of supralabials to level below centre of eye; (2) number of postrostrals; (3) number of dorsal scales between levels of axilla and groin; (4) number of ventral scales between levels of axilla and groin. Statistically significant differences between

N. quaggulus and *N. humilis* were observed in the number of postrostrals. *Norops uniformis* usually has 1-3 pale vertical lines in the flank region (lines can be broken), a character absent in *N. humilis* and *N. quaggulus* (Figures 1-3). *Norops quaggulus* differs from the other two species by usually having three large elongate scales in the anterior supraciliar region (only two such scales present in *N. humilis* and *N. uniformis*).

A discriminant function analysis based on three pholidotic characters (number of dorsal scales between levels of axilla and groin [DAG], number of ventral scales between levels of axilla and groin [VAG], and number of supralabial scales to level of centre of eye [supralabials]) yielded a scatter diagram (not shown) that correctly classified 59.5% of the specimens. A discriminant function analysis

based on five pholidotic characters (those above plus number of postrostral scales [postrostrals] and number of scales around midbody [SAM]) yielded a scatter diagram (Fig. 4) that correctly classified 71.8% of the specimens. The first and second discriminant functions classified 71.1% of the *N. quaggulus* specimens (group 1), 63.9% of the *N. humilis* specimens (group 2), and 82.8% of the *N. uniformis* specimens (group 3). Accordingly, the polygons of the three species largely overlap. The first function is $DS = -0.50732$ (supralabials) + 0.56861 (postrostrals) + 0.28199 (SAM) + 0.41253 (DAG) + 0.22297 (VAG). The second function is $DS = 0.37570$ (supralabials) + 0.49129 (postrostrals) + 0.65182 (SAM) - 0.16661 (DAG) - 0.59379 (VAG).

Key to *Norops humilis*, *N. quaggulus* and *N. uniformis*

- 1a Usually 22-32 dorsal scales between levels of axilla and groin, rarely up to 36; 6-10, mean 7.6, supralabial scales; flank usually with 1-3 pale vertical lines (lines can be broken); dewlap in adult males (in life) rose with purple spots *Norops uniformis*
- 1b Usually 30-39 dorsal scales between levels of axilla and groin, rarely few as 23; 5-8, mean 6.5, supralabial scales; flank without pale vertical lines or broken lines; dewlap in adult males (in life) different as above 2
- 2a Usually two large elongate scales in the anterior supraciliar region (Figure 5a); postaxillary pocket usually relatively wide, and shallow; hemipenis relatively large with well-developed elongate lobes and with a strongly calyculate surface on both the truncus and the lobes; maximum SVL 46.2 mm in males and 50.0 mm in females *Norops humilis*
- 2b Usually three large elongate scales in the anterior supraciliar region (Figure 5b); postaxillary pocket usually narrow, tube-like and deep; hemipenis relatively small with short and stout lobes and without a strongly calyculate surface on either the truncus or the lobes; maximum SVL 37.0 mm in males and 41.0 mm in females *Norops quaggulus*

Norops humilis (PETERS, 1863)

Anolis humilis PETERS, 1863: 138; type locality: Veragua, Panama.

Anolis humilis marsupialis TAYLOR, 1956: 97; type locality: 75 km WSW San Isidro de General, Costa Rica.

Geographic distribution: Central Costa Rica to Panama east of the Canal Zone (Fig. 9).

Diagnosis: *Norops humilis* can be distinguished from all other Central American species of *Norops*, except *N. compressicauda*, *N. quaggulus*, *N. tropidonotus*, *N. uniformis*, and *N. wampuensis*, by having a deep tube

Fig. 1. Adult Male of *Norops humilis* from Fortuna, Chiriquí, Panama.

Fig. 2. Adult Male of *Norops quaggulus* from Parque Nacional Saslaya, Nicaragua.

like axillary pocket. *Norops compressicauda*, *N. tropidonotus* and *N. wampuensis* have the scales anterior to the ear opening distinctly larger than those posterior to the ear opening (these scales more or less subequal in *N. humilis*). *Norops uniformis* has usually 1-3 pale vertical lines in the flank region (absent in *N. humilis*) and a rose male dewlap with a large central purple spot (male dewlap reddish orange with yellow margin in *N. humilis*). *Norops quaggulus* has usually three large elongate scales in the anterior supraciliar region (usually two such scales in *N. humilis*). Also, in *N. quaggulus* the hemipenis is relatively small with short and stout lobes and without a strongly calyculate surface on either the truncus or the lobes (the hemipenis of *N. humilis* is relatively large with well-developed elongate lobes and with a strongly calyculate surface on both the truncus and the lobes).

Description: Maximum SVL 43.9 mm in males, 48.0 mm in females; tail length / SVL ratio 1.33-1.70; HL / SVL 0.24-0.33 in males, 0.23-0.30 in females; HL / HW 1.39-1.62 in males, 1.38-1.65 in females; shank length / SVL 0.24-0.31; shank length / HL 0.78-1.19; longest toe of adpressed hind limb usually reaching to a point between posterior and anterior border of eye; tail slightly to distinctly laterally compressed in cross section, tail height / width ratio 1.13-1.47.

Scales on snout strongly keeled; 6-9 post-

rostrals (Fig. 6); 6-10 scales between nasals; usually 2 scales between circumnasal and rostral; scales in distinct frontal depression strongly keeled; supraorbital semicircles poorly to moderately developed, composed of keeled scales; 1-3, rarely 4, rows of scales separating supraorbital semicircles at narrowest point; 2-5 rows of scales separating supraorbital semicircles and interparietal at narrowest point; supraorbitals composed of 6-8 distinctly enlarged, strongly keeled scales; 1-2 enlarged supraorbitals in contact with supraorbital semicircles; supraorbitals decreasing abruptly in size laterally; 2-3 rows of granular scales between enlarged supraoculars and superciliaries at level of mid-orbit; usually 2 elongated superciliaries, the anterior one about two times the length of the following one; interparietal scale not well developed, only slightly enlarged relative to adjacent scales, surrounded by scales of moderate size; canthal ridge distinct, composed of 3-4 large scales; 7-12 scales present between second canthals; 7-13 scales present between posterior canthals; loreal region slightly concave, 22-46 strongly keeled loreal scales in a maximum of 4-8 horizontal rows; keeled subocular scales usually arranged in a single row; subocular series either in contact with supralabials or separated by one complete scale row; 5-8 supralabials to level below centre of eye; mental completely divided medially, bordered posteriorly by 5-8 postmentals; 5-8 infralabials to level below

Fig. 3. Adult Male of *Norops uniformis* from the Cockscomb Basin Wildlife Sanctuary, Stann Creek, Belize.

centre of eye; keeled granular scales present on chin and throat; lateral head scales anterior to the ear opening about the same size as those posterior to the ear opening; ear opening usually vertically oval.

Dorsum of body with keeled, subimbricate scales, 17-30 dorsal scales in one head length, 23-43 dorsal scales between levels of axilla and groin; 7-11 median rows of dorsal scales enlarged, dorsals abruptly larger than the smaller, keeled and homogeneous laterals; ventrals at midbody distinctly keeled, mucronate and subimbricate, 23-52 ventral scales in one head length, 32-57 ventral scales between levels of axilla and groin.

Dorsal, lateral and ventral caudal scales strongly keeled, without whorls of enlarged scales, although an indistinct division in segments is discernible; dorsal medial caudal scales slightly enlarged, not forming a crest; limb scales strongly keeled, imbricate; digital pads dilated, about two times as wide as non-dilated distal portion of toe; distal phalanx narrower than and raised from, dilated pad; 16-23 lamellae under phalanges ii-iv of fourth toe.

The completely everted hemipenis (SMF 80845) is a moderate-sized organ with well-developed elongate lobes (length of lobes equal to or slightly greater than length of truncus); both the truncus and the lobes have a strongly calyculate surface; sulcus spermaticus bifurcates at the base of the apex and the branches continue to the tip of the lobes.

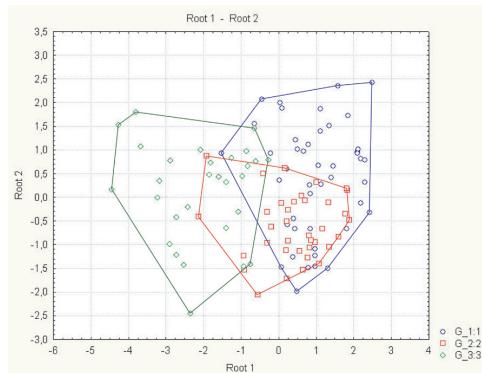

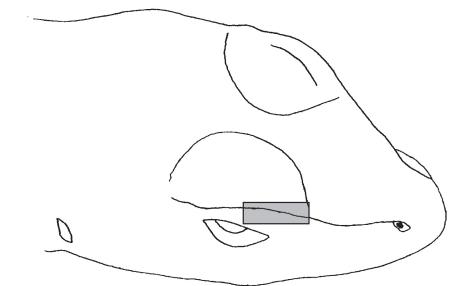

Fig. 4. Discriminant function analysis of Central American leaf litter anoles: 1) *Norops quaggulus*; 2) *Norops humilis*; 3) *Norops uniformis*. See text for details.

Norops quaggulus (COPE, 1885)

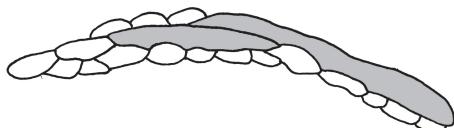

Anolis quaggulus COPE, 1885: 391; type locality: Río San Juan, Nicaragua.

Geographic distribution: Eastern Honduras to central Costa Rica (Fig. 9).

Diagnosis: *Norops quaggulus* can be distinguished from all other Central American species of *Norops*, except *N. compressicauda*, *N. humilis*, *N. tropidonotus*, *N. uniformis*, and *N. wampuensis*, by having a deep tube like axillary pocket. *Norops compressicauda*, *N. tropidonotus* and *N. wampuensis* have the scales anterior to the ear opening distinctly larger than those posterior to the ear opening (these scales more or less subequal in *N. quaggulus*). *Norops uniformis* has usually 1-3 pale vertical lines in the flank region (absent in *N. quaggulus*) and a rose male dewlap with a large central purple spot (male dewlap reddish orange with yellow margin in *N. quaggulus*). *Norops humilis* has usually two large elongate scales in the anterior supraciliar region (usually three such scales in *N. quaggulus*). Also, in *N. humilis* the hemipenis is relatively large with well-developed elongate lobes and with a strongly calyculate surface on both the truncus and

cave, 26-52 strongly keeled loreal scales in a maximum of 5-9 horizontal rows; keeled subocular scales usually arranged in a single row; subocular series either in contact with supralabials or separated by one complete scale row; 5-8 supralabials to level below centre of eye; mental completely divided medially, bordered posteriorly by 4-8 postmentals; 5-10 infralabials to level below centre of eye; keeled granular scales present on chin and throat; lateral head scales anterior to the ear opening about the same size as those posterior to the ear opening; ear opening usually vertically oval.

Fig. 9. Distribution of *Norops humilis* (squares) and *N. quaggulus* (triangles). Red symbols represent localities from where we have examined adult males with everted hemipenes; black symbols represent localities from where we have examined specimens of the respective species but not males with everted hemipenes; white symbols represent literature records. A single symbol can represent two or more nearby localities.

Dorsum of body with keeled, subimbricate scales, 19-29 dorsal scales in one head length, 26-42 dorsal scales between levels of axilla and groin; 7-11 median rows of dorsal scales enlarged, dorsals abruptly larger than the smaller, keeled and homogeneous laterals; ventrals at midbody distinctly keeled, mucronate and subimbricate, 26-44 ventral scales in one head length, 35-56 ventral scales between levels of axilla and groin.

Dorsal, lateral and ventral caudal scales strongly keeled, without whorls of enlarged scales, although an indistinct division in segments is discernible; dorsal medial caudal scales slightly enlarged, not forming a crest;

limb scales strongly keeled, imbricate; digital pads dilated, about two times as wide as non-dilated distal portion of toe; distal phalanx narrower than and raised from, dilated pad; 16-22 lamellae under phalanges ii-iv or fourth toe.

The completely everted hemipenis (SMF 79824) is a relatively small organ with short and stout lobes (length of lobes less than half the length of truncus); the truncus and lobes are not calyculate, but tiny papillae are present in many specimens, and these papillae are frequently black; the sulcus spermaticus bifurcates at the base of the apex and the branches continue to the tip of the lobes.

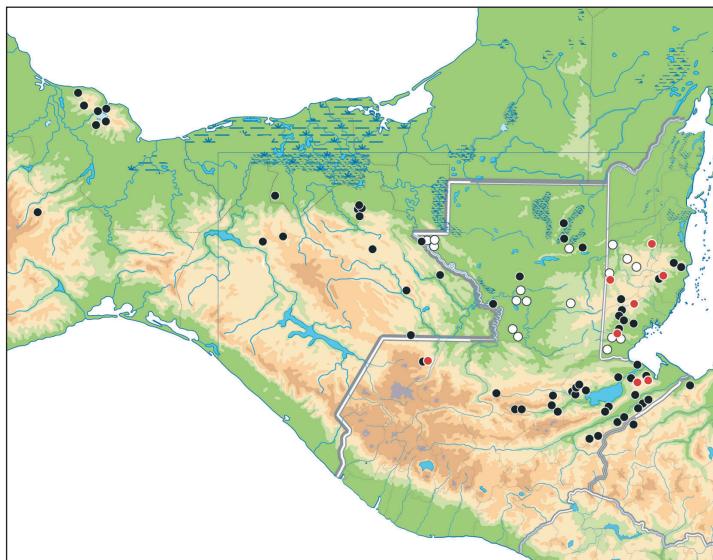

Fig. 10. Distribution of *Norops uniformis* (circles). Red symbols represent localities from where we have examined adult males with everted hemipenes; black symbols represent localities from where we have examined specimens of the respective species but not males with everted hemipenes; white symbols represent literature records. A single symbol can represent two or more nearby localities.

Norops uniformis (COPE, 1885)

Anolis uniformis COPE, 1885: 392; type locality: Yucatán.

Anolis ruthveni STUART, 1935: 310: 1; type locality: 2 mi. north of Santa Teresa, El Petén, Guatemala.

Geographic distribution: Southern Mexico including the Yucatán Peninsula to western Honduras (Fig. 10).

Diagnosis: *Norops uniformis* can be distinguished from all other Central American species of *Norops*, except *N. compressicauda*, *N. humilis*, *N. quaggulus*, *N. tropidonotus*, and *N. wampuensis*, by having a deep tube like axillary pocket. *Norops compressicauda*, *N. tropidonotus* and *N. wampuensis* have the scales anterior to the ear opening distinctly larger than those posterior to the ear opening (these scales more or less subequal in *N. uniformis*).

Norops humilis and *N. quaggulus* lack pale vertical lines in the flank region (usually present in *N. uniformis*) and have a reddish orange dewlap with yellow margin (male dewlap rose with a large central purple spot in *N. uniformis*).

Description: Maximum SVL 40.3 mm in males, 40.5 mm in females; tail length / SVL ratio 1.22-1.57; HL / SVL 0.24-0.38 in males, 0.22-0.30 in females; HL / HW 1.47-1.76 in males, 1.45-1.64 in females; shank length / SVL 0.25-0.31; shank length / HL 0.73-1.15; longest toe of adpressed hind limb usually reaching to a point between posterior and anterior border of eye; tail slightly to distinctly laterally compressed in cross section, tail height / width ratio 1.27-2.05.

Scales on snout strongly keeled; 5-8 postrostrals (Fig. 8); 6-10 scales between nasals; usually 2 scales between circumnasal and rostral; scales in distinct frontal depression strongly keeled; supraorbital semicircles poorly to moderately developed, com-

number of horizontal loreal scale rows		5-9 (6.78±1.02)	4-8 (6.24±0.95)	5-9 (6.72±1.13)
number of postrostrals		7-10 (7.93±0.81)	6-9 (7.30±0.73)	5-8 (6.28±0.10)
number of postmentals		4-8 (6.18±0.81)	5-8 (6.16±0.55)	4-8 (5.80±1.08)
number of scales between nasals		7-11 (8.26±1.07)	6-10 (8.14±1.08)	6-10 (7.83±0.97)
number of scales between 2nd canthals		v	7-12 (8.84±1.07)	7-10 (8.83±0.80)
number of scales between posterior canthals		8-15 (11.18±1.51)	7-13 (11.71±1.41)	8-13 (10.14±1.06)
Number of medial dorsal scales in one head length		19-29 (23.00±2.36)	17-30 (22.46±3.15)	18-25 (20.76±1.68)
Number of ventral scales in one head length		26-44 (32.20±4.14)	23-52 (32.24±6.65)	20-36 (29.97±3.83)
Number of medial dorsal scales between levels of axilla and groin		26-42 (33.78±3.81)	23-43 (33.73±5.20)	22-36 (28.10±3.90)
Number of ventral scales between levels of axilla and groin		35-56 (44.04±5.13)	32-57 (44.89±5.08)	31-47 (38.07±3.65)

Tab. 1. Selected measurements, proportions and scale characters of *Norops humilis*, *N. quaggulus* and *N. uniformis*. Range is followed by mean value and one standard deviation in parentheses, and then by sample size. Abbreviations: SVL = snout-vent length; HL = head length; HW = head width; SS = supraorbital semicircles; IP = interparietal plate; SO = subocular scales; SPL = supralabial scales, INL = infralabials.

posed of keeled scales; 1-3 rows of scales separating supraorbital semicircles at narrowest point; 1-4 rows of scales separating supraorbital semicircles and interparietal at narrowest point; supraorbitals composed of 6-8 distinctly enlarged, strongly keeled scales; 1-2 enlarged supraorbitals in contact with supraorbital semicircles; supraorbitals decreasing abruptly in size laterally; 2-3 rows of granular scales between enlarged supraoculars and superciliaries at level of mid-orbit; usually 2 elongated superciliaries, the anterior one about two times the length of the following one; interparietal scale not well developed, only slightly enlarged relative to adjacent scales, surrounded by scales of moderate size; canthal ridge distinct, composed of 3-4 large scales; 7-10 scales present between second canthals; 8-13 scales present between posterior canthals; loreal region slightly concave, 30-49 strongly keeled loreal scales in a maximum of 5-9 horizontal rows; keeled subocular scales usually arranged in a single row; subocular series either in contact with supralabials or separated by one complete scale row; 6-10 supralabials to level below centre of eye; mental completely divided medially, bordered posteriorly by 4-8 postmentals; 6-10 infralabials to level below centre of eye; keeled granular scales present on chin and throat; lateral head scales anterior to the ear opening about the same size as those posterior to the ear opening; ear opening usually vertically oval.

Dorsum of body with keeled, subimbricate scales, 18-25 dorsal scales in one head length, 22-36 dorsal scales between levels of axilla and groin; 7-11 median rows of dorsal scales enlarged, dorsals abruptly larger than the smaller, keeled and homogeneous laterals; ventrals at midbody distinctly keeled, mucronate and subimbricate, 20-36 ventral scales in one head length, 31-47 ventral scales between levels of axilla and groin.

Dorsal, lateral and ventral caudal scales strongly keeled, without whorls of enlarged scales, although an indistinct division in segments is discernible; dorsal medial caudal

scales slightly enlarged, not forming a crest; limb scales strongly keeled, imbricate; digital pads dilated, about two times as wide as non-dilated distal portion of toe; distal phalanx narrower than and raised from, dilated pad; 16-23 lamellae under phalanges ii-iv of fourth toe.

The completely everted hemipenis (USNM 496684) is a medium-sized bilobate organ; sulcus spermaticus bifurcates at base of apex and branches continue to tips of lobes; asulcale processus/ridge present; lobes strongly calyculate, truncus with transverse folds.
